

Subject Benefit-Cost Analysis

Project Name City of Shoreline SR 523 (N/NE 145th Street) & I-5 Interchange Improvements Project (Interchange

Project)

**Attention** Nytasha Walters, City of Shoreline

John McKenzie, Jacobs Susan Bartlett, Jacobs

From Dan Pitzler, Jacobs

**Date** May 4, 2020

The City of Shoreline (City) SR 523 (N/NE 145th Street) & I-5 Interchange Improvements Project (Interchange Project) will have significant impacts on the Community of Shoreline, the Seattle Metropolitan Area, and the United States, by relieving a congested corridor in the State of Washington. The Interchange Project is expected to decrease transportation costs, improve long term efficiency and reliability, and increase productivity, thereby helping the United States compete in the global economy.

This report describes the results of a benefit-cost analysis (BCA) for the proposed project.

## 1. Summary

## 1.1 Project Matrix

A project matrix the summarizes the benefits of the infrastructure improvements proposed for this project is provided in Table 1.

Table 1. Project Matrix – Summary of Infrastructure - Summary of Infrastructure Improvements and Associated Benefits

Current Status/Baseline and Problem to be Addressed	Change to Baseline or Alternatives	Types of Impacts
The existing 145th Street and I-5 Interchange is a congested bottle neck for vehicles (with a failing level of service), and a high collision location for vehicles, cyclists, and pedestrians (with an accident rate three times the regional average). Zoning to support increased residential densities in this area and regional data indicates continued and significant growth in this area that will further exacerbate conditions and place additional demands on the facility. Due to its high level of congestion, transit agencies have historically largely avoided providing service on the 145 <sup>th</sup> corridor. Due to its proximity to the Interchange Project and the positive benefit to it, the No Build Alternative would include a Business Access and Transit (BAT) Lane from 5 <sup>th</sup> Avenue to 12 <sup>th</sup> Avenue (a separate Sound Transit project) to improve westbound access to the future Shoreline South/145th Station (light rail), but no changes at other signalized intersections.	The preferred design concept for the SR-523 (N/NE 145th Street) & I-5 Interchange Improvements Project would replace two signalized intersections with modern roundabouts. These improvements will increase capacity through the two most congested intersections along the SR-523 corridor. The Build Alternative would include an improved sidewalk and landscaping along the north side of 145 <sup>th</sup> Street from 5 <sup>th</sup> Avenue to 12 <sup>th</sup> Avenue as part of Sound Transit's Bus Rapid Transit (BRT) project, and a bus access and turn lane from approximately 6 <sup>th</sup> Ave NE to west of 8 <sup>th</sup> Ave NE.	This project would substantially reduce delay to automobile drivers and passengers, truck drivers, bus passengers, pedestrians and cyclists. Further it would improve safety by reducing the frequency and severity of vehicular, pedestrian, and bicycle collisions. The reduced delay would result in fuel cost savings and emissions reductions. Finally, the project will result in a modest reduction in long-term signal maintenance costs.

## 1.2 Project Cost

The estimated initial capital costs for the project are provided in Table 2.

Table 2. Initial Capital Costs of Alternatives (2019\$)

		Build									
Cost Item	No Build	NE 145th Project	Sound Transit BRT Project	Total Build Alternative							
Planning	\$1,020,000	\$1,200,000	\$800,000	\$2,000,000							
Design	\$3,170,000	\$3,300,000	\$2,200,000	\$5,500,000							
Right of Way	\$9,500,000	\$2,000,000	\$1,800,000	\$3,800,000							
Construction	\$22,000,000	\$18,500,000	\$17,900,000	\$36,400,000							
Total	\$35,690,000	\$25,000,000	\$22,700,000	\$47,700,000

## 1.3 Project Benefits and Costs

The benefits from this project include reduced travel time, vehicle, pedestrian, and bicycle collisions, and emissions. The costs include design and construction costs and the cost of long-term maintenance of traffic signals. There could be some differences in the long-term cost of pavement maintenance however the differences in road, sidewalk, and landscaping maintenance are likely to be quite minor between the alternatives and were not quantified. Other benefits and costs not quantified and discussed in Section 4.6 include travel time reliability, modal diversion, work zone impacts, emergency vehicle mobility and reliability, and improved resilience.

A summary of the benefits and costs of the project compared to the No Build alignment is shown in Table 3 at a 7% real discount rate. As shown, net benefits are positive: \$981.9 million with a benefit-cost ratio of 104.6.

A sensitivity analysis of the results at a 3% real discount rate is shown in Table 4. At a 3% discount rate, net benefits are greater than at a 7% discount rate. This is because most costs occur relatively soon, and benefits are realized throughout the analysis period: when the discount rate is lower, future benefits are discounted less thus resulting in higher net benefits.

The calculations of the benefits and costs analysis results in an extraordinarily high Benefit-Cost ratio. This is due to two main factors for consideration.

- 1) The Build Alternative costs are relatively low compared to the No-Build Alternative. The No Build Scenario includes considerable investments by Sound Transit to enable their future Bus Rapid Transit (BRT) line to avoid traffic congestion at the interchange project location, including several blocks of widening the roadway for a bus-only and right-turn lane. Many of these improvements by Sound Transit would not be implemented in the Build Alternative due to the travel time benefits to BRT buses gained in the Build Alternative.
- 2) **Travel time benefits from the roundabouts are significant**. The interchange is a highly congested bottle neck for this regional corridor, and volumes are expected to increase due to the future light rail station, high-density redevelopment around the light rail station, and regional growth. Traffic modeling and analysis for the proposed roundabouts predict substantial travel time benefits from this alternative.

In summary, this project presents a uniquely beneficial project to the Puget Sound region for improving transportation capacity, mobility, and safety for buses, pedestrians, bikes, and vehicles.

Table 3. Summary, Present Value of Benefits and Cost (7% real discount rate)

	Build Alternative
Benefits	
Residual Value Benefit	\$481,000

Travel Time Saving	\$1,460,382,000
Collision Cost Savings	\$3,604,000
Fuel Cost Reduction	\$239,004,000
Emissions Cost Reduction	\$67,000
Total Benefits	\$1,704,815,000
Total Costs	\$11,045,000
Net Benefit	\$1,693,770,000
Benefit-Cost Ratio	153.4

## 2. Introduction

The existing 145th Street and I-5 Interchange (Figure 1) is a congested bottle neck for vehicles (with a failing level of service), and a high accident location for vehicles, cyclists, and pedestrians (with a collision rate three times the regional average). Currently, 145th Street (SR 523) crosses over I-5 on an existing bridge deck with two narrow 6-foot sidewalks, two eastbound and two westbound travel lanes (each 11-12 feet wide), and a center lane with westbound and eastbound left-turn pockets. The existing interchange left turn pockets are inadequate to handle existing traffic volumes — with queues spilling back into the east and west bound travel lanes causing significant traffic back-ups. The existing sidewalks are substandard and narrow for the amount of pedestrian and bicycle traffic predicted by the opening of the new light rail station in 2024.

Figure 1. Project Location Map

The problems in the interchange area are predicted to get worse. Regional data indicates continued and significant growth in this area that will further exacerbate conditions and place additional demands on the facility. Shoreline neighborhoods around the Shoreline South/145th Station have been upzoned for high-density transit-oriented development. Due to its high level of congestion, transit agencies have historically largely avoided providing service on the 145<sup>th</sup> corridor.

## 3. Description of Alternatives

Both the No Build and Build alternatives assume the Lynwood Link Extension project, providing light-rail services from Northgate to Snohomish County will proceed. That project will include a light rail station just north of the proposed intersection improvements for this project. Further, both projects assume transit service changes planned by King County Metro and Sound Transit will occur with changes in ridership that are common to both the No Build and Build alternatives. The intersection simulation models used to project volumes and delay for autos, trucks, bicycles, and pedestrians for this project also assumed these future changes to transit infrastructure and service.

## 3.1 No Build Alternative

The No Build Alternative includes a series of infrastructure improvements planned by Sound Transit as part of its many ongoing regional mobility improvement programs. Sound Transit is committed to providing Bus Rapid Transit (BRT) Service to/from the future light rail station along 145<sup>th</sup> Street. In the No Build scenario, the Sound Transit improvements include a west-bound business access and transit (BAT) lane for transit speed and reliability, north sidewalk, and landscaping on 145<sup>th</sup> Street from 12<sup>th</sup> Avenue NE to 5<sup>th</sup> Avenue NE, a signalized intersection at 5<sup>th</sup> Avenue, and matches to the Lynwood Link Extension improvements east of 5<sup>th</sup> Avenue NE.

### 3.2 Build Alternative

The City of Shoreline led a multi-agency study to develop an innovative conceptual design for the interchange that addressed current and future concerns which were brought into the current design phase for detailed analysis with partners. The preferred design concept for the SR-523 (N/NE 145th Street) & I-5 Interchange Improvements Project would replace two signalized intersections with modern roundabouts (see Figure 2). These improvements will increase capacity through the two most congested intersections along the SR-523 corridor.

Figure 2. 145<sup>th</sup> Street Project Concept

Roundabout-controlled intersections have been demonstrated to improve safety by reducing the number of injury collisions (practically eliminating serious accidents by removing head-on and right-angle collisions) while also reducing delays for all travel modes. The existing I-5 bridge connecting these two intersections will be reconfigured from a 5-lane bridge to a 4-lane bridge and the excess space will be re-utilized for a sizeable shared pedestrian and bicycle path crossing I-5.

In addition, the Build Alternative would include an improved sidewalk along the north side of 145th Street from 6th Avenue to west of 8<sup>th</sup> Avenue as part of Sound Transit's BRT project, as well as a relatively short, BAT lane from just east of 6<sup>th</sup> Ave NE to west of 8<sup>th</sup> Ave NE. The length of the BAT lane for Sound Transit's BRT project would be considerably reduced in the Build Alternative because of the travel time benefits for transit speed and reliability that is achieved from the roundabouts at the interchange.

## 4. Benefits

This section describes quantified benefits (and disbenefits) of the proposed project, including residual value, travel time savings, collision cost reductions, fuel cost reductions, emissions reductions, and signal maintenance cost savings. Other qualitative benefits are described as well.

Project benefits are assumed to begin with the initial year of operations, 2024, and extend for 30 years, through 2053. Travel volumes and delay for autos and trucks were estimated using various modeling software (VISSIM, Synchro, and Sidra) with a future year of 2042. Because travel volumes and delay are uncertain beyond the end of the modeling horizon, this benefit-cost analysis keeps annual benefits from 2043 to 2053 fixed at 2042 levels.

### 4.1 Residual Value

The intersection improvements are estimated to have a 50-year useful life, which extends well beyond the end of the 30-year analysis period. To account for the value that extends beyond the analysis period, it was assumed that the assets will depreciate linearly, and the remaining useful life of the capital cost is added as a benefit (negative cost) in the last year of the analysis, 2054. That benefit is then discounted to the present like all other benefits and costs. The net present value of the intersection improvements is \$481,000 (Build Alternative minus No Build) as shown in Table 5.

Table 5. Residual Value, Present Value (2019\$)

	Residual Value
Residual Value Benefit – No Build Alternative	\$1,431,000
Residual Value Benefit – Build Alternative	\$1,912,000
Net Residual Value	\$481,000

## 4.2 Travel Time Savings

The project will result in travel time savings by individuals traveling in multiple modes: estimates have been prepared for autos and trucks, buses, and bicycles and pedestrians. The value of travel time savings was calculated in accordance U.S. DOT guidance: 2017 values were escalated to 2019 dollars using the two-year change (Q1 2017 – Q1 2019) in the gross domestic product (GDP) deflator of 3.8%. The results are \$15.37 per person-hour (2019\$) for all purpose local travel (autos and transit), which assumes that 95.4% of trips are personal and 4.6% of trips are business. Travel time savings for other modes are as follows: \$29.70 for truck drivers and \$30.63 for pedestrian and bicycles. Sections 4.2.1-4.2.3 describe the methodology used to estimate delay for autos and trucks, transit riders, and bicyclists and pedestrians. Section 4.4 reports estimated travel time savings for each travel mode.

### 4.2.1 Auto and Truck Delay Calculations

Annual delay for autos and heavy vehicles (trucks and buses) in the project area is shown in Table 6. Volumes and delays at intersections in the project area were modeled during the NE 145<sup>th</sup> Street Intersection Control Evaluation study (145<sup>th</sup> ICE study)<sup>1</sup> with follow-up modifications to reflect the most recent version of the build alternative. In that study, the City of Shoreline, Sound Transit and WSDOT reviewed the Puget Sound Regional Council (PSRC) travel demand model's (4K Models) 2040 forecasts, the forecasts used in Shoreline's 145th Corridor Study and in Sound Transit's Stage 2 forecasts to develop 2042 AM and PM peak hour forecasts. To estimate opening year 2024 traffic, a straight-line projection was developed using the 2017 existing traffic counts and the 2042 forecasts.

Estimated annual delay for intersections in the project area for the No Build Alternative in 2017 and 2042 and for the Build Alternative in 2017, 2025, and 2042 are shown in Table 6 (2025 results were interpolated to the 2024 project start date). As noted in that table, expansion factors of 3.0 and 6.0, respectively, were used to estimate delay for a 12-hour "AM" period and a 12-hour "PM" period. These were estimated using the results of one-week hourly traffic counts at 6 locations at intersections in the project area a summary of which is shown in Table 7. As shown in Table 7, this methodology aligned delay to the relationship between volume in an off peak hour to volume in the peak hour as follows: No delay if an off-peak hour's volumes are 70% or less than peak volumes, 50% delay if an off-peak hour's volumes are 70%-90% of peak hour volumes, and 100% of delay if an off-peak hour's volumes are 90% or higher than peak hour volumes. In Table 6, the hours of annual delay at each intersection is calculated as follows:

peak hour volumes \* delay (in seconds) / 360 \* the off-peak hour expansion factors \* annual expansion factor

Lochner, Prepared for the City of Shoreline. NE 145<sup>th</sup> Street Intersection Control Evaluation Report. Draft April 2019.

Source: Summary of traffic counts at project intersections, Lochner. October and December, 2017.

The annual expansion factor means that average annual delay is calculated by multiplying average daily delay by 255.

Table 7 also shows off-peak expansion factors used to estimate annual transit delay. In the last columns of table, traffic counts are shown for a 3-hour peak period and off-peak. We used this information estimate that each off-peak transit passenger experiences 0.2 times the delay of a trip made during the AM peak and 0.4 times the delay of a trip made during the PM peak. The 145<sup>th</sup> St ICE study reports that heavy vehicles (trucks and buses) represent 3.5 percent of all vehicle traffic in the project area. Jacobs estimates that 90 percent of the heavy vehicle trips are trucks and 10 percent of the trips are buses. (This estimate is needed because other data sources are used to estimate bus transit passenger travel time savings.) Thus, for the volumes show in Table 6, 96.5 percent are assumed to be cars and 3.15 percent are assumed to be trucks.

For passenger vehicles, an average vehicle occupancy of 1.68 from US DOT benefit-cost guidance is used to calculate delay experienced by individuals<sup>2</sup>.

## 4.2.2 Transit Ridership and Delay Calculations

Delay experienced by transit riders was calculated based on data developed as part of the Lynwood Link Extension work approved by the Federal Transit Administration as part of Sound Transit's New Starts submittal process. Annual ridership for the No Build and Build Alternatives and estimated delay in 2016, 2025, and 2042 are shown in Table 8 (2025 results were interpolated to the 2024 project start date). That table shows estimated daily ridership, outbound and inbound, during 3-hour AM and PM peaks and off-peak periods using 2016 service and projected services in 2042. Annual ridership is calculated using an expansion factor of 303 for King County Metro routes (the 512 only) and 290 for Sound Transit routes (all other routes).

Delay per rider was estimated by DKS and Associates 2019 for Sound Transit's SR 522 and 145th Street BRT Projects. Off-peak delay was estimated using the daily traffic count information shown in Table 7 and described in Section 4.2.1. 2016 delay was estimated to be 67 percent of 2042 delay which is the ratio between the aggregated 2017 and 2042 delay estimates shown in Table 6. Total annual delay in 2016 and 2042 is calculated by multiplying daily delay by 365. 2024 and 2025 annual delay is calculated by interpolating between 2016 and 2042.

## 4.2.3 Bicycle and Pedestrian Delay Calculations

For the purposes of this analysis, bicycle and pedestrian crossings and crossing times are estimated for the No Build and Build Alternatives at the two intersections where the roundabouts are proposed (NE 145<sup>th</sup> St and 5<sup>th</sup> Ave NE and NE 145<sup>th</sup> St and I-5 SB ramps).

Current intersection crossings were estimated using traffic counts during the PM peak hour during the 2017 traffic counts referenced in Section 4.2.1. The 2042 intersection crossings during the PM peak hour were estimated using the modeling for the 145<sup>th</sup> ICE study. Average crossing times were developed assuming a pedestrian walking 3.5 ft per second, no added delay at roundabouts, and 30 seconds added delay for signalized crossings. Daily pedestrian crossings were estimated using a peak-daily expansion factor of 4.0 and 300 days per year of crossings (Jacobs estimates).

As shown in Table 9, annual bicycle and pedestrian crossing times in 2042 are estimated to be 38,247 hours in the No Build Alternative and 12,327 hours in the build alternative.

Days per Year 300 Source: Jacobs estimates

Note: No crossing allowed today for west leg of 145th St @ SB I-5 ramp: thus this leg is excluded from estimates

Note: Crossing times based on a pedestrian walking 3.5 ft per second, no added delay at roundabouts, and 30 seconds added delay for signalized crossings.

## 4.2.4 Total Travel Time Savings

The present value of travel time savings by mode are shown in Table 10. As shown, the 30-year present value benefit of annual travel time savings in 2019 dollars is \$847.7 million.

Table 10. Present Value of Travel Time Savings, 2024-2053 (7% real discount rate)

	Travel Time Savings
No Build Delay, Autos	\$2,083,824,000
No Build Delay, Trucks	\$98,658,000
No Build Delay, Buses	\$77,280,000
No Build Delay, Bicycle and Pedestrians	\$7,842,000
Build Delay, Autos	\$1,323,315,000
Build Delay, Trucks	\$62,652,000
Build Delay, Buses	\$31,160,000
Build Delay, Bicycle and Pedestrians	\$2,794,000
Total Travel Time Savings	\$847,682,000

### 4.3 Vehicle Collision Cost Reductions

The estimated reduction in vehicle collisions resulting from the project are shown in Table 11. A collision modification factor of 0.79 is used for converting a signalized intersection to a roundabout. Five-year collision history in the project vicinity was used to represent historical collision frequencies. It was assumed that collisions per vehicle would remain constant through time which implies that collisions will increase proportional to volumes all other things being equal. Projected volume increases (from Section 4.2.1) are used to estimate future collisions. The dollar value of reduced vehicle injuries and property damages are taken from US DOT benefit-cost guidance. The present value of vehicle collision cost reductions is shown in Table 12.

The estimates shown in this section reflect collisions from all travel modes: no attempt to break out bicycle and pedestrian from motor vehicle collisions was made. It's possible that a more in-depth analysis with separated crash modification factors for vehicles compared to bicycles and pedestrians could result in slightly different collision cost estimates. Further, the vehicle travel time saving estimates shown in Table 10 and the collision cost estimates shown in Table 11 do not account for the impact of collisions on travel delay. The reduction in collisions resulting from the Build Alternative would result in reduced delay associated with collisions. As a result, the monetized benefits shown in this analysis are conservative and likely understate the actual benefits of the Build Alternative.

Total Vehicle Collision Cost Savings	\$1,937,000

### 4.4 Vehicle Operating Costs

For the Interchange Project any change in vehicle operating costs will be small and too difficult to measure with any degree of accuracy. Vehicles may travel slightly fewer feet with a roundabout compared to a signalized intersection, but there may be slightly more tire wear associated with the roundabout. Thus, no changes in vehicle operating costs are estimated for this analysis.

### 4.5 Fuel Cost Reductions

Fuel cost reductions for autos and trucks are estimated using the following parameters and sources:

- \$3.50 per gallon gasoline and \$3.46 per gallon for diesel: AAA Gas Prices for Seattle-Bellevue-Tacoma, July 7, 2019<sup>3</sup>.
- Fleet average fuel economy of 23.6 miles per gallon for cars, from AAA Your Cost of Driving<sup>4</sup>, 2019, and 6.4 miles per gallon for trucks from An Analysis of the Operational Costs of Trucking, 2018 update<sup>5</sup>.
- Fleet average fuel economy was multiplied by 28.3 percent which is the ratio of fleet average fuel economy at 5 miles per hour (to simulate delay conditions) and 50 miles per hour (for fleet average conditions) from California Air Resources Board CO2e methodology<sup>6</sup>.

Fuel use was converted to gallons per hour assuming 5 miles per gallon and multiplied by annual delay estimates for autos as trucks (see Section 4.2.1). The present value of fuel cost savings for autos and trucks is shown in Table 13. As shown, the present value of estimated fuel cost savings is \$141 million.

https://gasprices.aaa.com/?state=WA, Accessed July 7, 2019.

https://exchange.aaa.com/automotive/driving-costs/ Accessed July 7, 2019.

<sup>&</sup>lt;sup>5</sup> American Transportation Research Institute. <a href="https://atri-online.org/wp-content/uploads/2018/10/ATRI-Operational-Costs-of-Trucking-2018.pdf">https://atri-online.org/wp-content/uploads/2018/10/ATRI-Operational-Costs-of-Trucking-2018.pdf</a> Accessed July 7, 2019.

<sup>&</sup>lt;sup>6</sup> https://ww3.arb.ca.gov/msei/onroad/downloads/pubs/co2final.pdf Accessed July 7, 2019.

Table 13. Present Value of Fuel Cost Savings 2024-2053, (7% real discount rate)

	Fuel Cost Savings
No Build – Autos	\$355,177,000
No Build – Trucks	\$31,632,000
Build – Autos	\$225,552,000
Build – Trucks	\$20,088,000
Total Fuel Cost Savings	\$141,169,000

Fuel cost reductions for buses are not estimated because the fuel mix of the future bus fleet is highly uncertain. Thus, quantified project benefits may be understated somewhat.

### 4.6 Emissions Reductions

Burning fuel results in air emissions that can damage human health and property. Table 14 shows the dollar value of emissions from U.S. DOT guidance. Those values were multiplied by the tons of each pollutant with delay converted to pollutants using grams per mile for autos and trucks traveling at an average speed of 5 miles per hour (used to estimate idling and low speeds during delay conditions).

Emission factors of criteria pollutants, including volatile organic compounds (VOC), carbon monoxide (CO), nitrogen oxides (NOx), particulate matter from vehicles travel and idling in the project study area were estimated using California Department of Transportation's CT-EMFAC2017 program for 2025 and 2042 using Emission factors were obtained using EMFAC2017 using vehicle category LDA for autos and T6 utility, diesel for trucks<sup>7</sup>. The emission factors for autos and trucks, in grams, are shown in Table 15. Those factors are converted to tons, then multiplied by hours of delay (from Section 4.2.1, 2025 results were interpolated to the 2024 project start date).

The present value of emissions cost reductions is shown in Table 16. As shown, there would be a modest reduction of \$41,000 in emissions associated with the Build Alternative.

Table 14. Dollar Value of Emission Reductions (2019\$)

Pollutant	Monetary Value			
NO <sub>x</sub> Emission	\$8,618	Per ton		
PM <sub>2.5</sub> Emission	\$392,287	Per ton		
SO <sub>2</sub> Emission	\$50,775	Per ton		
VOC Emission	\$2,077	Per ton		
Greenhouse gas emissions <sup>a</sup>	\$1-\$2	Per metric tonne

### 4.6.1 Benefits Not Addressed Quantitatively

## 4.6.1.1 Travel Time Reliability

The proposed interchange is expected to provide a benefit for passenger vehicles and other commuters during peak hour periods, by significantly reducing congestion and bottlenecks during these periods. With the reduction in congestion and bottlenecks during these peak periods, it is expected that the variation in the amount of time that vehicles are held up along this corridor will be significantly reduced. In particular, this benefits transit service and transit passengers to have more predictable and reliable arrival times and travel times.

The US DOT benefit-cost guidance states that "At this time, USDOT does not have a specific recommended methodology for valuing reliability benefits in BCA. If applicants nevertheless choose to present monetized reliability improvements in their analysis, they should carefully document the methodology and tools used, and clearly explain how the parameters used to value reliability are separate and distinct from the value of travel time savings used in the analysis." While the City believes the build alternative would result in noteworthy travel time benefits, this study does not attempt to monetize those benefits because of the complexity and uncertainty associated preparing those estimates.

### 4.6.1.2 Modal Diversion

While the volume of traffic along the 145<sup>th</sup> Street corridor is expected to be relatively consistent with or without the preferred alternative, the pedestrian improvements in the project area support the planned increase in bus and light rail boardings by Sound Transit, which will reduce automobile traffic in other areas, with associated savings in vehicle operating costs, accidents, and emissions. It is questionable if the planned transit increases would be achieved to the levels anticipated without these improvements, but data was not available about the potential for modal diversion away from automobiles. Thus, this potential benefit was not quantified in this analysis.

## 4.6.1.3 Work Zone Impacts

While any construction project will generally lead to some traffic delays during construction, the City intends to undertake measures during the construction to mitigate or reduce these delays, primarily by avoiding construction activities during peak volume periods. By avoiding construction during peak periods traffic delay during construction is likely to be relatively minor and was not quantified in this analysis. To the extent construction delay during construction occurs, the quantified net benefits for this project will be overstated somewhat.

Table 16. Present Value of Emissions Cost Reductions (2019\$)

PM2.5	\$2,000
Total Emissions	
No Build	\$3,319,000
Build	\$3,278,000
Total Emissions Reductions	\$41,000

## 4.6.1.4 Emergency Vehicle Mobility and Reliability

The intersection improvements will lessen delay and improve reliability for emergency vehicles traveling through the project area. Emergency vehicle volumes for the Build and No Build alternatives were unavailable for this study. Thus, the time savings associated with emergency vehicles is likely understated for circumstances when seconds may be important to an emergency response.

### 4.6.1.5 Quality of Life

The proposed improvements are expected to improve the quality of life in the area by making facilities more ADA accessible, making walking and cycling a more pleasant experience, and other factors. These benefits are difficult to reliably monetize, and thus have been described qualitatively.

## 5. Costs

The initial capital costs associated with the No Build and Build Alternatives are shown in Table 17. As shown the No Build Alternative is estimated to cost \$35.7 million and the Build Alternative is estimated to cost \$47.4 million. It is important to note that the No Build alternative includes costs for Sound Transit's Bus Rapid Transit improvements to achieve bus transit speed and reliability that would not be implemented in the Build Alternative due to the speed and reliability benefits gained by the roundabouts.

Table 17. Initial Capital Costs of Alternatives (2019\$)

		Build					
Cost Item	No Build	NE 145th Project	Sound Transit BRT Project	Total Build Alternative			
Planning	\$1,020,000	\$1,200,000	\$800,000	\$2,000,000			
Design	\$3,170,000	\$3,300,000	\$2,200,000	\$5,500,000			
Right of Way	\$9,500,000	\$2,000,000	\$1,800,000	\$3,800,000			
Construction	\$22,000,000	\$18,500,000	\$17,900,000	\$36,400,000			
Total	\$35,690,000	\$25,000,000	\$22,700,000	\$47,700,000			
Source: Jacobs compilation of estimates prepared for Sound Transit and Shoreline, 2019.							

During operations there will be a long-term savings in maintenance costs related to replacing two signals with the roundabouts. Historical data from the City of Shoreline suggest an annual maintenance cost of about \$10,000 per signal which corresponds to a present value of savings during the 2024-2053 period of \$189,000.

There could be some differences in the long-term cost of pavement maintenance however the differences in road, sidewalk, and landscaping maintenance are likely to be quite minor between the alternatives and were not quantified.

## 6. Summary of Benefits and Costs

The calculations of the benefits and costs analysis results in an extraordinarily high Benefit-Cost ratio. This is due to two main factors for consideration. 1) **The Build Alternative costs are relatively low compared to the No Build Alternative**. The No Build Scenario includes considerable investments by Sound Transit to enable their future Bus Rapid Transit (BRT) line avoid the traffic congestion at the interchange project location, including several blocks of widening the roadway for a bus lane. The length of BAT lane in the Build Alternative would be significantly reduced because of the travel time benefits to BRT buses gained by the roundabouts in the Build Alternative. 2) **Travel time benefits from the roundabouts are significant**. The interchange is a highly congested bottle neck for this regional corridor, and volumes are expected to increase due to the future light rail station and high-density redevelopment around the light rail station. Traffic modeling and analysis for the proposed roundabouts predict substantial travel time benefits from this alternative.

A summary of the benefits and costs of the project compared to the No Build alignment is shown in Table 18 at a 7% real discount rate. As shown, net benefits are positive: \$981.9 million with a benefit-cost ratio of 104.6.

Table 18. Summary, Present Value of Benefits and Cost (7% real discount rate)

	Build Alternative
Benefits	
Residual Value Benefit	\$481,000
Travel Time Saving	\$847,682,000
Collision Cost Savings	\$1,937,000
Fuel Cost Reduction	\$141,169,000
Emissions Cost Reduction	\$41,000
Total Benefits	\$991,310,000
Total Costs	\$9,384,000
Net Benefit	\$981,926,000
Benefit-Cost Ratio	104.6

A sensitivity analysis of the results at a 3% real discount rate is shown in Table 19. At a 3% discount rate, net benefits are higher than at a 7% discount rate (\$1.7 billion). This is because most costs occur relatively soon, and benefits are realized throughout the analysis period: when the discount rate is lower, future benefits are discounted less thus resulting in higher net benefits.

Table 19. Summary, Present Value of Benefits and Cost, (3% real discount rate)

	Build Alternative
Benefits	
Residual Value Benefit	\$1,758,000
Travel Time Saving	\$1,460,382,000
Collision Cost Savings	\$3,604,000
Fuel Cost Reduction	\$239,004,000
Emissions Cost Reduction	\$67,000
Total Benefits	\$1,704,815,000
Total Costs	\$11,045,000
Net Benefit	\$1,693,770,000
Benefit-Cost Ratio	153.4

The annual benefits and costs in 2019\$ are shown in Table 20.
